EXPERIMENT 07

Breadth-First Search (BFS)

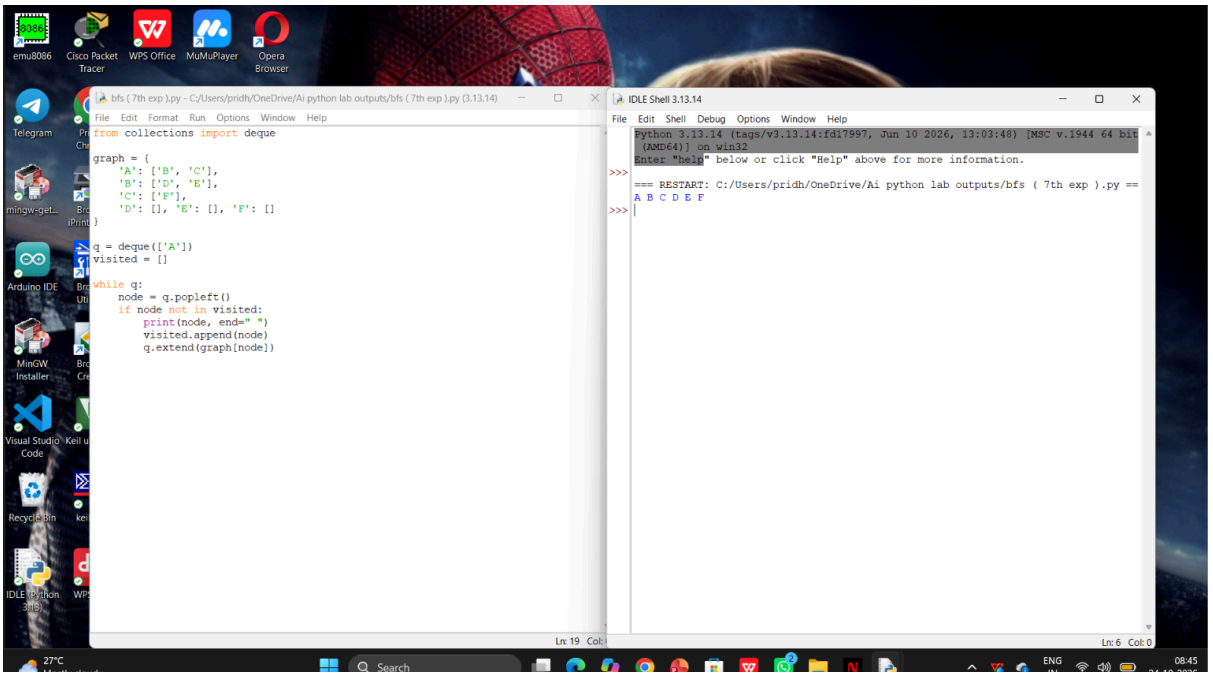

Aim:

To write a Python program to implement Breadth-First Search for graph traversal.

Algorithm:

- Create a graph using an adjacency list.
- Initialize a queue with the starting node.
- Mark the starting node as visited.
- Remove a node from the front of the queue and display it.
- Add its unvisited adjacent nodes to the queue.
- Repeat until the queue becomes empty.

Program output :

Result:

Thus, the Python program to implement Breadth-First Search was executed successfully.
